## Abstract

Controlling pain after total joint **arthroplasty** (TJA) is critical to minimizing complications, decreasing costs, and expediting patients' return to function. We implemented a TJA multimodal **pain management** protocol at a Level III **trauma center** in a small, **rural community** in New York. We retrospectively reviewed 266 patient charts and collected patient demographics, pain management information, and discharge data. Our primary goals were to quantify the total number of **narcotic** medication doses used and length of hospital stay. The multimodal pain management protocol significantly reduced the number of narcotic doses used ( $P < .01$ ). Hospital length of stay decreased slightly; although not statistically significant ( $P = .25$ ), this may be clinically significant. Gender, age, and type of arthroplasty (ie, knee, hip) were not significant factors. A multimodal approach to pain management after TJA can reduce narcotic use and hospital length of stay, thereby also reducing the incidence of side effects from narcotics.
